# SCXI 8-Channel Isolated Analog Input M odules 

## NI SCXI-1125, NI SCXI-1120, NI SCXI-1120D

- 8 channels
- $333 \mathrm{kS} / \mathrm{s}$ maximum sampling rate
-Gain and lowpass filter settings per channel
- Up to $300 \mathrm{~V}_{\text {rms }}$ working isolation per channel
- Signal inputs from $\pm 2.5 \mathrm{mV}$ to $\pm 1000$ VDC with TBX-1316
-NI-DAQ driver software simplifies configuration, measurement and scaling

## SCXI-1125

- Programmable gain and filter settings
- $300 \mathrm{~V}_{\text {rms }}$ working isolation per channel,

## SCXI-1120, SCXI 1120D

- Jumper selectable filter per channel - 4 Hz and 10 kHz filter (SCXI-1120) - 4.5 kHz and 22.5 kHz (SCXI-1120D) - $250 \mathrm{~V}_{\text {rms }}$ working isolation per channel

Operating Systems
-Windows 2000/NT/XP
Rec ommended Softw are
-LabVIEW

- LabWindows/CVI
- M easurement Studio
- VI Logger

Driver Softw are
-NI-DAQ 7
Calibration Certificate Included See page 21.

## Overview

The National Instruments SCXI-1125, SCXI-1120, and SCXI-1120D are 8-channel isolated analog input modules. These modules share a common architecture, providing 250 to $300 \mathrm{~V}_{\text {rms }}$ of working isolation and lowpass filtering for each analog input channel. This architecture is ideal for amplification and isolation of millivolt, volt, 0 to 20 mA , 4 to 20 mA , and thermocouple signals. Each module can multiplex these eight channels into a single channel of the DAQ device, and you can add modules to increase channel count. These modules also offer parallel mode operation for increased scanning rates.

## Analog Input <br> SCXI-1125

The analog inputs of the NI SCXI-1125 consist of eight programmable isolation amplifiers. You can program each channel independently for input ranges from $\pm 2.5 \mathrm{mV}$ to $\pm 5 \mathrm{~V}$. With the SCXI-1313 high-voltage attenuator terminal block, the in put range is extended to $\pm 300 \mathrm{~V}$. With the TBX-1316, the input range is extended to $\pm 1000$ V DC ( $680 \mathrm{~V}_{\text {rms }}$ ). Each channel also includes a programmatic lowpass filter that you can configure for 4 Hz or 10 kHz . With the SCXI-1125 you can perform random scanning meaning you can select only the channels from which you want to acquire data as well as scan channels in any order. Each channel is individually isolated with a working common-mode voltage of $300 \mathrm{~V}_{\text {rms }}$ between channels or channel to earth. In addition, the SCXI-1125 is CE certified as double insulated, Category II, for $300 \mathrm{~V}_{\text {rms }}$ of operational isolation.

## SCXI-1120, SCXI-1120D

The analog inputs of the NI-1120/D consist of eight isolation amplifiers. You can configure each amplifier using jumpers for input ranges from $\pm 2.5 \mathrm{mV}$ to $\pm 5 \mathrm{~V}$ (SCXI-1120) or $\pm 5 \mathrm{mV}$ to $\pm 10 \mathrm{~V}$ (SCXI-1120D). With the SCXI-1327 high-voltage attenuator terminal block, the input range is extended to $\pm 250 \mathrm{~V}$. With theTBX-1316, the input range is extended to $\pm 1000 \mathrm{VDC}\left(680 \mathrm{~V}_{\text {rms }}\right)$. Each channel also includes a lowpass filter that is jumper configurable for 4 Hz or 10 kHz (SCXI-1120), or for 4.5 or 22.5 kHz (SCXI-1120D). Each channel is individually isolated with a working common-mode voltage of $250 \mathrm{~V}_{\text {rms }}$ between channels or channel to earth. In addition, the SCXI-1120 and SCXI-1120D are CE certified as double insulated, Category II, for $250 \mathrm{~V}_{\text {rms }}$ of operational isolation.

## Cold-J unction Compensation

Each of these modules can read the cold-junction sensor from the SCXI-1320, SCXI-1321, SCXI-1327, SCXI-1328, and TBX-1328 terminal blocks. TheSCXI-1125 can scan the sensor along with other channels, but the SCXI-1120/D must read the cold-junction sensor as a separate analog input operation. This is commonly done once before the start of a continuous acquisition.

## Calibration

TheSCXI-1125 contains calibration hardware to null out error sources. With programmable offset calibration, software programmable analog switches ground the inputs of each of the instrumentation amplifiers for offset error calibration. An onboard EEPROM stores the calibration constants for each channel for each input range in a user-defined area. The EEPROM also stores a set of factory calibration constants in permanent memory, and cannot be modified. NI-DAQ driver software transparently uses the calibration constants to correct for gain and offset errors.

# Multifunction DAQ and SCXI Signal Conditioning Accuracy Specifications Overview 

## Every M easurement Counts

There is no room for error in your measurements. From sensor to software, your system must deliver accurate results. NI provides detailed specifications for our products so you do not have to guess how they will perform. Along with traditional data acquisition specifications, our E Series multifunction data acquisition (DAQ) devices and SCXI signal conditioning modules include accuracy tables to assist you in selecting the appropriatehardware for your application.

To calculate the accuracy of NI measurement products, visit ni.com/accuracy

## Absolute Accuracy

Absolute accuracy is the specification you use to determine the overall maximum tolerance of your measurement. Absolute accuracy specifications apply only to successfully calibrated DAQ devices and SCXI modules. There are four components of an absolute accuracy specification:

- Percent of Reading - is a gain uncertainty factor that is multiplied by the actual input voltage for the measurement.
- Offset - is a constant value applied to all measurements.
- System Noise - is based on random noise and depends on
the number of points averaged for each measurement (includes quantization error for DAQ devices).
-Temperature Drift - is based on variations in your ambient temperature.
- Input Voltage - the absolute magnitude of the voltage input for this calculation. The fullscale voltage is most commonly used.

Based on these components, the formula for calculating absolute accuracy is:

Absolute Accuracy $= \pm[($ Input Voltage $X \%$ of Reading $)+$ (Offset + System Noise + Temperature Drift)]

Absolute Accuracy RTI ${ }^{1}=($ Absolute Accuracy Input VoItage $)$ ${ }^{1} \mathrm{RTI}=$ relative to input

Temperature drift is already accounted for unless your ambient temperature is outside 15 to $35{ }^{\circ} \mathrm{C}$. For instance, if your ambient temperature is at $45^{\circ} \mathrm{C}$, you must account for $10^{\circ} \mathrm{C}$ of drift. This is calculated by:

Temperature Drift $=$ Temperature Difference $\mathrm{x} \%$ Drift per ${ }^{\circ} \mathrm{C} \times \operatorname{Input}$ Voltage

## Absolute Accuracy for DAQ Devices

Absolute Device Accuracy at Full Scale is a calculation of absolute accuracy for DAQ devices for a specific voltage range using the maximum voltage within that rangetaken one year after calibration, the Accuracy Drift Reading, and the System Noise averaged value.

Below is the Absolute Accuracy at Full Scale calculation for the NI PCI-6052E DAQ device after one year using the $\pm 10 \mathrm{~V}$ input range while averaging 100 samples of a 10 V input signal. In all the Absolute Accuracy at Full Scale calculations, we assume that the ambient temperature is between 15 and $35{ }^{\circ} \mathrm{C}$. Using the Absolute Accuracy table on the next page, we see that that the calculation for the $\pm 10 \mathrm{~V}$ input range for Absolute Accuracy at Full Scale yields 4.747 mV . This calculation is done using the parameters in the same row for one year Absolute Accuracy Reading, Offset and Noise + Quantization, as well as a value of 10 V for the input voltage value. You can then see that the calculation is as follows:

$$
\text { Absolute Accuracy }= \pm[(10 \times 0.00037)+947.0 \mu \mathrm{~V}+87 \mu \mathrm{~V}]= \pm 4.747 \mathrm{mV}
$$

In many cases, it is helpful to calculate this value relative to the input (RTI). Therefore, you do not have to account for different input ranges at different stages of your system.

$$
\text { Absolute Acuracy RTI }=( \pm 0.004747 / 10)= \pm 0.0475 \%
$$

The following example assumes the same conditions except that the ambient temperature is $40^{\circ} \mathrm{C}$. You can begin with the calculation above and add in the Drift calculation using the \% Drift per ${ }^{\circ} \mathrm{C}$ from Table 2 on page 196.

$$
\begin{gathered}
\text { Absolute Accuracy }=4.747 \mathrm{mV}+\left(\left(40-35^{\circ} \mathrm{C}\right) \times 0.000006 /{ }^{\circ} \mathrm{C} \mathrm{X} \mathrm{10V}\right)= \pm 5.047 \mathrm{mV} \\
\text { Absolute Acuracy RTI }=( \pm 0.005047 / 10)= \pm 0.0505 \%
\end{gathered}
$$

## Absolute Accuracy for SCXI M odules

Below is an example for calculating the absolute accuracy for the NI SCXI-1102 using the $\pm 100 \mathrm{mV}$ input range while averaging 100 samples of a 14 mV input signal. In this calculation, we assume the ambient temperature is between 15 and $35^{\circ} \mathrm{C}$, so Temperature Drift $=0$. Using the accuracy table on page 313, you find the following numbers for the calculation:

> Input Voltage $=0.014$
> $\%$ of Reading $\mathrm{M} \mathrm{ax}=0.02 \%=0.0002$
> Offset $=0.000025 \mathrm{~V}$
> System Noise $=0.000005 \mathrm{~V}$
> Absolute Accuracy $= \pm[(0.014 \times 0.0002)+0.000025+0.000005] \mathrm{V}= \pm 32.8 \mu \mathrm{~V}$
> Absolute Accuracy RTI $= \pm(0.0000328 / 0.014)= \pm 0.234 \%$

The following example assumes the same conditions, except the ambient temperature is $40^{\circ} \mathrm{C}$. You can begin with the Absolute Accuracy calculation above and add in the Temperature Drift.

[^2]Absolute Accuracy RTI $= \pm(0.00003815 / 0.014)= \pm 0.273 \%$

# Multifunction DAQ and SCXI Signal Conditioning Accuracy Specifications Overview 

For both DAQ devices and SCXI modules, you should use the Single-Point System Noise specification from the accuracy tables when you are making single-point measurements. If you are averaging multiple points for each measurement, the value for System Noise changes. The Averaged System Noise in the accuracy tables assumes that you average 100 points per measurement. If you are averaging a different number of points, use the following equation to determine your Noise + Quantization:

System Noise $=$ Average System Noise from table $x \sqrt{(100 / \text { number of points })}$

For example, if you are averaging 1,000 points per measurement with the PCI-6052E in the $\pm 10 \mathrm{~V}( \pm 100 \mathrm{mV}$ for the SCXI-1102) input range, System Noise is determined by:

> NI PCI-6052E $* *$
> System Noise $=87.00 \mu \mathrm{~V} \times \sqrt{(100 / 1000)}=27.50 \mu \mathrm{~V}$
> NI SCXI-1102
> System Noise $=5 \mu \mathrm{~V} \times$ SQRT $\sqrt{(100 / 1000)}=1.58 \mu \mathrm{~V}$
**The System Noise specifications assume that dithering is disabled for single-point
measurements and enabled for averaged measurements.

See page 21 or visit ni.com/calibration for more information on the importance of calibration on DAQ device accuracy.

## Absolute System Accuracy

Absolute System Accuracy represents the end-to-end accuracy including the signal conditioning and DAQ device. Because absolute system accuracy includes components set for different input ranges, it is important to use Absolute Accuracy RTI numbers for each component.

Total System Accuracy RTI $= \pm$ SQRT [(Module Absolute Accuracy RTI)2

+ (DAQ Device Absolute Accuracy RTI)2]

The following example calculates the Absolute System Accuracy for the SCXI-1102 module and PCI-6052E DAQ board described in the first examples:

Total System Accuracy RTI $= \pm \sqrt{[(0.00273) 2+(0.000505) 2]}= \pm 0.278 \%$

## Units of M easure

In many applications, you are measuring some physical phenomenon, such as temperature. To determine the absolute accuracy in terms of your unit of measure, you must perform three steps:

1. Convert a typical expected value from the unit of measure to voltage
2. Calculate absolute accuracy for that voltage
3. Convert absolute accuracy from voltage to the unit of measure

Note: it is important to use a typical measurement value in this process, because many conversion algorithms are not linearized. You may want to perform conversions for several different values in your probable range of inputs, rather than just the maximum and minimum values.

For an example calculation, we want to determine the absolute system accuracy of an NI SCXI-1102 system with a NI PCI-6052E, measuring a J-type thermocouple at $100^{\circ} \mathrm{C}$.

1. A J-type thermocouple at $100^{\circ} \mathrm{C}$ generates 5.268 mV (from a standard conversion table or formula)
2. The absolute accuracy for the system at 5.268 mV is $\pm 0.82 \%$. This means the possible voltage reading is anywhere from 5.225 to 5.311 mV .
3. Using the same thermocouple conversion table, these values represent a temperature spread of 99.3 to $100.7^{\circ} \mathrm{C}$.

Therefore, the absolute system accuracy is $\pm 0.7^{\circ} \mathrm{C}$ at $100^{\circ} \mathrm{C}$.

## Benchmarks

The calculations described above represent the maximum error you should receive from any given component in your system, and a method for determining the overall system error. However, you typically have much better accuracy values than what you obtain from these tables.

If you need an extremely accurate system, you can perform an end-to-end calibration of your system to reduce all system errors. However, you must calibrate this system with your particular input type over the full range of expected use. Accuracy depends on the quality and precision of your source.

We have performed some end-to-end calibrations for sometypical configurations and achieved the results in Table 1:

To maintain your measurement accuracy, you must calibrate your measurement system at set intervals over time.

For a current list of SCXI signal conditioning products with calibration services, please visit ni.com/calibration

Table 2. NI PCI-6052E Analog Input Accuracy Specifications
Note: Accuracies are valid for measurements following an internal (self) E Series calibration. Averaged numbers assume averaging of 100 single-channel readings. M easurement accuracies are listed for operational temperatures within $\pm 1{ }^{\circ} \mathrm{C}$ of internal calibration temperature and $\pm 10^{\circ} \mathrm{C}$ of external or factory-calibration temperature. One-year calibration interval recommended. The absolute accuracy at full scale calculations were performed for a maximum range input voltage (for example, 10 V for the $\pm 10 \mathrm{~V}$ range) after one year, assuming 100 point averaging of data.
